‘Robert Livermore’, a Persian Walnut Cultivar with a Red Seedcoat

Gale McGranahan1 and Chuck Leslie
Department of Pomology, University of California, Davis, CA 95616

Additional index words. Juglans regia L., breeding, anthocyanidin

This new persian walnut (Juglans regia L.) cultivar ‘Robert Livermore’, tested as UC91-75-15, is distinguished by a red seedcoat (testa or pellicle) (Fig. 1). In all other respects it is typical of commercially available persian walnut (Juglans regia L.) cultivars.

**Origin**

‘Robert Livermore’ is derived from a controlled cross-pollination between UC86-11 and ‘Howard’, a cultivar released by the University of California in 1978 (Fig. 2). ‘Howard’ (Plant Pat. No. 4,388) has typical extra light or light kernels. UC86-11 is a germplasm introduction obtained as scionwood identified as RA1088 from the walnut collection of the Institut National de la Recherche Agronomique, Station de Recherches d’Arboriculture Frutière, Bordeaux, France). On the introduction papers RA 1088 is described as “Juglans purpurea à cerneau rouge”. Krussmann (1984) describes a J. regia variety ‘Purpurea’ with dull red leaves and another variety ‘Rubra’ as having a red nutmeat and a blood-red epidermis. The parent, UC86-11, has a reddish brown seedcoat and a typical light cream-colored kernel. Both parents and offspring have the typical green leaves of J. regia. Thus neither the reddish parent nor the offspring fit those descriptions.

The cross made in 1991 resulted in 14 surviving progeny of which six had the red seedcoat and six had the typical light tan seedcoat and two have not yet produced flowers. Other crosses made with UC86-11 resulted in a progeny ratio of 106 red: 119 tan, χ² = 0.75, p = 0.39. Although the red color in the progeny ranges from light pink to dark reddish brown, it appears that the presence of pigment coloration is inherited as a single dominant gene, R, present in the heterozygous condition in UC86-11.

**Description**

‘Robert Livermore’ was selected from among the progeny, all grown on University of California, Davis, field plots, because it was relatively precocious, blooming in the fourth year from germination. About 90% of the lateral buds are fruitful and estimated yield is good but not outstanding. ‘Robert Livermore’ leaves out and blooms near ‘Chandler’ time and is ready to harvest about one week earlier. The pollen shedding period of ‘Robert Livermore’ overlapped the pistillate bloom in three out of four years. Other satisfactory pollenizers would be ‘Tulare’ and ‘Cisco’.

The nut has a strong shell and a good seal. The shell is well-filled and the kernel is quite easy to extract. The kernel (7.0 g) makes up 50% of the total nut weight (14.1 g). These values are averages of seven years of data collection as described in Forde and McGranahan (1996). The seedcoat is a red, 39-11 to 39-14 on the Munsell scale (Munsell Color, Macbeth Color and Photometry Division, Baltimore, Md.) All the nuts produced have the same color red seedcoat because the seedcoat is maternal tissue. The color has been attributed to anthocyanidins (Bruce Campbell, personal communication). This cultivar is expected to serve niche markets.

**Availability**

‘Robert Livermore’ has been granted U.S. Plant Patent 12,264. The rights are assigned to the Regents of the University of California, Oakland, and nurseries are invited to apply for a license. Grafting wood is available from the authors.
